# Utilizing Crowd Intelligence for Online Detection of Emotional Distress

Master's Thesis Presentation

Siddhant Goel Advisor: Han Xiao

Supervisor: Prof. Dr. Claudia Eckert

Chair for IT Security
Technische Universität München

March 13, 2013

#### Outline

- Introduction
  - Backdrop
  - Motivation
  - Problem Definition
- Theoretical Background
  - Machine Learning and Text Classification
  - Support Vector Machines
  - Ensemble Learning methods
- Experimental Results
  - Experiments
  - Results
- Conclusion and Future Work
- Q/A

### Backdrop

- Millions of people die every year because of suicide
- Most people are between 15 to 29 years old
- Rise of social media Twitter, Facebook, Reddit, Wordpress
- Sections of interest on Reddit "/r/happy" <sup>1</sup> and "/r/suicidewatch" <sup>2</sup>
- Sections of interest on Twitter the entire website
- People want to post their inner feelings on the web
- **Direct phrases** "thoughts of suicide make me happy", "I have a rope around my neck"
- Indirect phrases "I don't know anything anymore", "Need someone to talk to"

<sup>1</sup>http://www.reddit.com/r/happy

<sup>2</sup>http://www.reddit.com/r/suicidewatch

# Backdrop

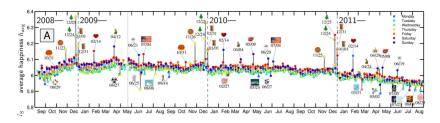

Figure: Happiness on Twitter as a function of time

- Study conducted in 2011
- 46 billion words collected over 33 months
- Negativity on Twitter has been on the rise
- Words include death, hate, and even suicide

### Motivation

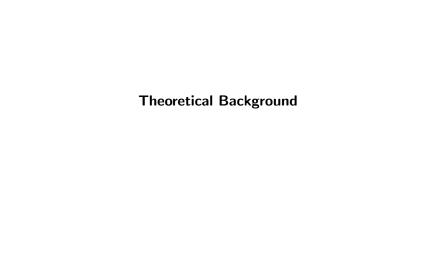

Figure: Last tweet of Twitter user "@CapitalSTEEZ\_"3

- Some accounts have lots of followers, some don't
- Lives can be saved if there is a surveillance system of suicide
- Public sentiment information available on the web + No analysis possible = Disconnect

<sup>3</sup>http://twitter.com/CapitalSteez\_

### Problem Definition

- Evaluate machine learning algorithms that can be used for identifying depressed emotions in pieces of text
- Build a web based system that can
  - tap into crowd intelligence to incrementally improve the classifiers
  - detect content on the web that indicates that its author may be depressed or suicidal

# Machine Learning

- Algorithms that can learn from data
- Construct a model from a given dataset, and then perform the required task on another dataset
- Supervised learning Train the models on the training data, and predict on the test data
- Unsupervised learning No distinction between training and test data

### Text Classification

- Subset of machine learning algorithms (we focus on supervised text classification)
- Given some pieces of text, put unseen pieces of text into two or more categories
- Dataset  $\{(\mathbf{x_n}, y_n)\}_{n=1}^N$  containing N instances
- Each instance  $(\mathbf{x_n}, y_n)$  is of the form  $[(x_{n,1}, x_{n,2}, ..., x_{n,D}), y_n]$
- Supervised learning calculate  $y_n$  of test data given information about  $y_n$  from training data
- Unsupervised learning calculate  $y_n$  given only information about  $\mathbf{x_n}$

# Support Vector Machines

- Fairly popular class of algorithms used for binary classification
- Given training data in some *D* dimensional space, find a decision boundary (hyperplane) that separates the two classes
- Maximize the distance of the boundary from any data point
- Decision function depends on a (usually small) subset of points called support vectors
- Kernel (linear/polynomial/RBF/Sigmoid) functions used to calculate distance between two points

### Linear kernel SVM

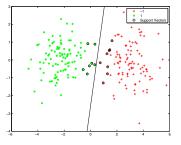

Figure: Binary classification on a dataset using a linear kernel SVM

### Kernel functions

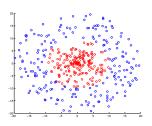

Figure: Dataset in 2D (cannot be classified using a linear kernel SVM)

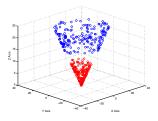

Figure : Dataset transformed to 3D

# Ensemble Learning

- Class of machine learning methods that combine models to obtain better predictions
- Performance not guaranteed to be better than constituent classifiers
- Ensemble methods still usually outperform individual classifiers
- Soft requirement underlying models should be diverse
- Various strategies to combine models select best, voting, boosting, stacking

# Bagging

- Combine M classifiers to form a single classifier
- To predict, obtain predictions from all constituent classifiers, and take majority vote
- Requirement classifiers should change for even small changes in underlying classifiers
- Two main approaches for training individual classifiers
  - Sample split different samples for different classifiers
  - Feature split different features for different classifiers

# Boosting

- Assign each sample a weight value (same for all samples in the beginning)
- Train M classifiers successively
- Each classifier focuses more on samples that the previous classifier classified incorrectly
- For each classifier, calculate  $\epsilon$  (measure of error) and  $\alpha$  (decreases with  $\epsilon$ )
- Final prediction =  $sign(\sum_{n=1}^{m} \alpha_{m} y_{m}(\mathbf{x_{n}}))$

# Stacking

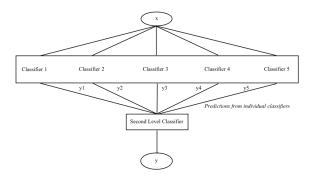

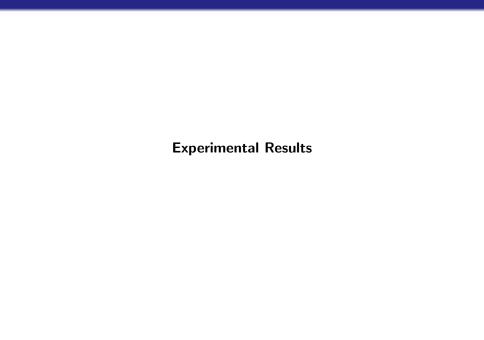

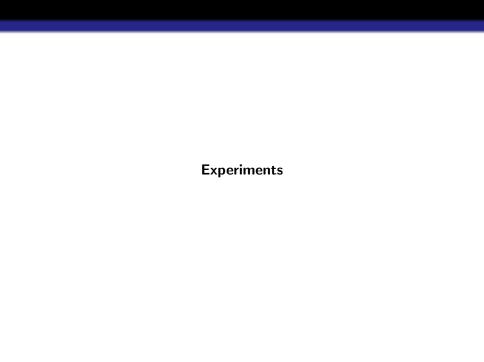

Figure: Prediction using a stacking ensemble

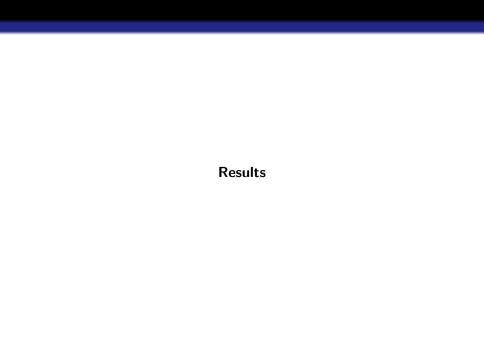

- Outputs from first layer form the input for second layer
- Layer-1 classifiers can be trained using bootstrapping or selecting random features

#### **Approach**

- Implement all the models in MATLAB
- Extract n-grams (size upto 2) out of the Kaggle dataset
- Use tf-idf information as feature values
- Input matrix 6182 rows and 23175 columns
- SVM, Bagging, Boosting, Stacking obtain accuracy (10-fold cross validation) against number of samples
- SVM Growth of number of support vectors with the number of samples
- Bagging Accuracy against number of underlying models
- Start with 100 samples, and continue adding 100 samples on each iteration until no more samples are left

#### **Support Vector Machines**

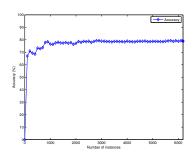

Figure : Accuracy v/s Number of instances

- Linear kernel accuracy -79.02%
- Polynomial/RBF/Sigmoid kernel accuracy - 34.39%
- Having more features implies no need for a kernel function

#### **Support Vector Machines**

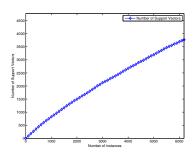

Figure : Number of support vectors v/s Number of instances

- 100 samples 90% support vectors
- 6182 samples 60% support vectors
- Less support vectors implies that the classification is easy

### Bagging

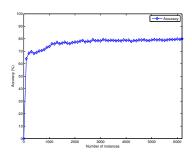

Figure : Accuracy v/s Number of instances

- 9 linear kernel SVMs underneath
- Performance ultimately governed by how SVMs perform
- Average accuracy on all 6182 samples = 79.65%

### Bagging

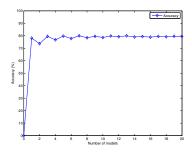

Figure : Accuracy v/s Number of models

- Accuracy "stabilizes" slowly with the number of models
- Each model is assigned a random subset of samples
- Increase in number of models implies Subsets overlap implies Performance stabilizes

### **Boosting**

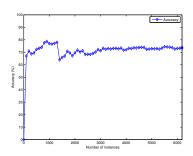

Figure : Accuracy v/s Number of instances

- 9 linear kernel SVMs trained successively on each iteration
- Average accuracy = 72.84%

### **Stacking**

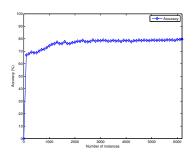

Figure : Accuracy v/s Number of instances

- 9 linear kernel SVMs at first level
- Average accuracy = 79.48%

#### **Approach**

- Implement all the models in Python, and web interface in Django
- No training data available => build our own
- Training data
  - comes from Reddit
  - "/r/happy" users posts their happy moments
  - "/r/suicidewatch" users post when they want to commit suicide
  - pull 500 stories from each, every day
- Prediction data
  - should be the general sentiment of the overall public
  - hence. Twitter
  - pull 100 tweets every 3 hours

#### Data consolidation frequencies

Fetch 1000 posts from Reddit	24 hours
Fetch 100 tweets from Twitter	3 hours
Re-assign labels to previous tweets and update statistics	24 hours

#### **Architecture**

Figure: Landing page

- two sections *Ratings* and *Monitoring*
- Ratings used to build the training data
- Monitoring used to monitor the status of the models and check distressed tweets

#### Ratings module

Figure : Landing page of the Ratings module

- taps into crowd intelligence
- automated scripts fetch 1000 posts from Reddit every day
- displays the first unlabelled post
- users can then assign labels to stories
- this builds the training data

#### Monitoring module

Figure : Landing page of the Monitoring module

- displays the top few tweets that were classified as depressed by all the classifiers
- links for checking the status of individual classifiers

#### Monitoring module

Figure : Statistics of the bagging classifier

For each classifier -

- displays the overall level of distress (in %) on Twitter
- each bubble displays
  - the number of stories that were found depressed on that particular day
  - the first tweet from that day which was depressed (no confidence values, yet)

### Conclusion

- An evaluation of Support Vector Machines and Ensemble Learning methods (Bagging/Boosting/Stacking) in the domain of text classification
- Bagging outperformed Stacking outperformed SVM outperformed Boosting
- A web based system that can detect emotional distress on Twitter
- No labels implies qualitative evaluation is difficult except observation
- Observed results seem to be reasonable

### Future Work

- Fetch more tweets
- Increase the crowd intelligence involved
- Relabelling process (decreases wastage of resources)
- Select best performing model
- Store confidence values
